Abstract

The rapid growth of IoT devices in recent years has shaped everyday life more profoundly than most technological advancements in history. As with any widespread innovation, this global adoption brings both benefits and drawbacks. The conveniences introduced by IoT and smart devices are now integral to modern life, making them difficult for society to forgo. However, the rising number of these devices also opens up more potential attack surfaces for malicious actors. When considering that many of these devices accompany individuals nearly constantly, the threat to personal privacy rises substantially.

This project focuses on one specific aspect of the problem: its objective is to prevent the unauthorized recording of sensitive conversations through microphones. The selected methodology to achieve the objective is to execute a Denial of Service (DoS) attack on the microphones by overwhelming them with ultrasonic sound waves. To demonstrate the effectiveness of this method, a fully functional prototype device capable of executing the attack has been developed.

This report provides a detailed explanation of each step in the development process, starting with the analysis of microphone technologies and a review of state-of-the-art attacks targeting them, followed by the formulation of the core concept, and concluding with its final implementation. To facilitate a deeper understanding of its functionality, the report includes a comprehensive explanation of each component and of the source code.

The prototype device has been thoroughly tested on the most common types of devices, including smartphones, PCs, and smartwatches, across various distance ranges, and has demonstrated highly promising results. The report concludes with an analysis of the known issues and of the areas that could be further improved in the future in order to deliver a product even more effective, reliable and feature-rich.

CHAPTER 1

Introduction

1.1 Report introduction

In recent years, there has been a rapid proliferation of devices equipped with microphones, such as smartphones, smart speakers, and smartwatches. This has led to a significant decline in user privacy, especially as many of these devices come with an 'always-listening' feature enabled by default. As a result, the security vulnerabilities in microphones have attracted the attention of both attackers and defenders: while the motivations of the former are self-evident, the latter, in an interesting role reversal, can leverage these vulnerabilities to enhance user privacy. In other words, it is possible to execute an attack that disables nearby microphones to preserve the privacy of users who may be unaware of potential eavesdropping.

From the perspective of improving user privacy by exploiting microphones' vulnerabilities, this project investigates Denial of Service (DoS) attacks on microphones, with the goal of understanding the underlying technologies, identifying vulnerabilities, and replicating attacks on real hardware. The project seeks to provide a comprehensive analysis of microphone manufacturing technologies, evaluate the state-of-the-art in attack techniques, and explore the limitations and implications of these attacks. In particular, the project will focus on a specific type of DoS attack, which involves flooding the target microphone with ultrasound waves to prevent it from recording any conversation. Additionally, a fully functioning prototype device capable of executing the attack has been developed. As we navigate through both the software and hardware implementations of the project, an analysis of the results will be presented, assessing the strengths and weaknesses of the prototype device.

1.2 Report description

The remainder of the document is organized as follows:

- Chapter 2: This chapter offers a comprehensive overview of the project's theoretical background, detailing the key features of various microphone technologies and examining known attack methods.
- Chapter 3: This chapter provides a general overview of the project's implementation, offering the reader a simple description of the prototype device's components and capabilities.
- Chapter 4: This chapter presents a detailed explanation of the device, covering everything from its initial design to its physical construction and realization.

-
- Chapter 5: This chapter outlines the results obtained and proposes ideas for potential improvements to the device in future work.
 - Chapter 6: This chapter recaps with a high-level summary what has been done in the project.

CHAPTER 2

Background

This section of the report will introduce to the reader the most relevant microphone technologies, highlighting their core features and primary domains of use.

Furthermore, the different types of known DoS attacks on microphones will be reviewed, evaluating the advantages and disadvantages of each. This analysis will justify the selection of the chosen attack method for the project.

2.1 Microphone Technologies

Microphones are critical components in many modern devices, enabling audio capture for communication, recording, and interaction with digital assistants. Since they are used in a wide range of devices, their underlying technology must meet diverse requirements, resulting in both horizontal diversification and vertical improvement over the past century.

While acknowledging the historical significance of early microphone implementations, this report will focus only on the most commonly used models today, as they are most relevant to the development of the project.

2.1.1 Dynamic Microphones

A dynamic microphone is a type of mic that converts sound waves into electrical signals using electromagnetic induction thanks to a special component, the permanent magnet. The permanent magnet can either be a metal coil or a 'ribbon transducer': when the sound waves hit the microphone, the magnet will move, resulting in the generation of an electrical signal. This type of microphone is known for its durability, ability to handle loud environments, and tolerance of background noise. Additionally, it does not require external power, making it a versatile option for various situations. Although it may not be as sensitive or well-suited for recording high-frequency sounds, it is ideal for live music events and concerts involving loud sounds.

2.1.2 Condenser Microphones

Often referred to as the 'cousins' of dynamic microphones, condenser microphones generate electrical signals from sound waves through the use of a capacitor. The capacitor consists of two charged metal plates, one of which is movable. When a sound wave strikes the diaphragm (the movable plate), the distance between the plates changes, producing an electrical signal that corresponds to the sound captured. While condenser microphones require an electrical current to charge the plates and are more

sensitive to environmental conditions compared to dynamic microphones, they excel at capturing high-frequency sounds and vocals, delivering crisp, detailed, and high-quality audio. These qualities make condenser microphones ideal for studio recording, as they are best suited for quiet environments and require the external power source.

2.1.3 Electret Condenser Microphones

The electret condenser microphone is a subtype of the standard condenser microphone. The key difference is that, while standard condenser microphones require a power supply to maintain the electrical charge, electret microphones use an electret material to keep the capsule charged. This type of material is one that carries a permanent electrical charge sealed within an insulating film. Since electret microphones don't require an external power source to charge the plates, they tend to be less expensive than standard condenser microphones, making them ideal for use in consumer electronics and mobile devices.

2.1.4 Micro-Electro-Mechanical Systems Microphones

MEMS microphones is another subtype of the standard condenser microphone which shares many characteristics with the electret type one. However, in this case, the transducer is a microscopic component that integrates seamlessly with the microscopic semiconductor-based components in an integrated circuit. This allows for smaller devices, making them suitable for an even wider range of applications, such as smartphones, tablets, laptops, hearing aids, voice biometric, digital voice assistants, and more. Additionally, compared to electret microphones, MEMS microphones can offer superior audio performance, though they tend to be more susceptible to mechanical and electrical noise.

2.2 Microphone Attacks

Having explored the landscape of microphone technologies, it is evident that the ones we encounter most frequently in daily life are Electret microphones, and even more commonly, MEMS microphones. Both technologies share key components, namely the membrane and the capacitor, each of which is vulnerable to specific types of attacks that can effectively prevent microphones from recording conversations intended to remain private.

The membrane can be made to vibrate by flooding the microphone with sound waves, thereby overwriting the sound waves from the conversation and preventing proper recording. Meanwhile, the capacitor can be targeted by altering its electric charge, causing it to produce a distorted or different electrical signal instead of the original one.

The following section will examine known DoS attacks that exploit the vulnerabilities of these two components, evaluating each attack technique in terms of its suitability for the project.

2.2.1 Electromagnetic Pulse Attack

A general EMP attack involves releasing a burst of electromagnetic radiation capable of disrupting or destroying electronic equipment and systems across the target area. It is frequently employed in modern warfare with the goal of causing infrastructural disruption, targeting communication systems, computers, vehicles, and other critical equipment.

When using an EMP to disable microphones, the strategy involves emitting a powerful burst of electromagnetic radiation that overwhelms and potentially damages the electronic components within the microphones. This could result in the microphones failing to generate the intended electrical signals, or even becoming completely non-functional, thus disabling their ability to record or transmit audio.

The severity of the impact would depend on the intensity and proximity of the EMP, potentially leaving affected microphones unusable until they are repaired or replaced.

While theoretically the most effective method on paper, employing an EMP for this project is impractical for several reasons. First and foremost, health concerns must be taken into account, as this type of attack could pose risks to nearby individuals with pacemakers, hearing aids, or other medical devices. Secondly, it would lack control over the range of action and the potential impact on targets. Additionally, testing the prototype device would be extremely difficult, with results that could be highly unpredictable and the testing targets potentially suffering permanent damage. Finally, the need for high power sources makes it unsuitable for embedded devices.

2.2.2 Laser Injection Attack

Luminous attacks on microphones involve using lasers to disrupt or damage their functionality. Lasers emit focused beams of intense light that can interfere with microphones in several ways. First, a powerful laser beam can overload the microphone's optical or electronic sensors, causing them to register false signals. Second, laser light can interfere with the microphone's ability to accurately capture sound waves, potentially distorting or disrupting the audio signal. In extreme cases, particularly with high-powered lasers, the intense heat generated by the beam can physically damage the microphone's components, such as diaphragms, sensors and circuitry. Moreover, luminous attacks can compromise privacy by remotely activating microphones through light-based signals, thereby bypassing traditional security measures.

However, this type of attack does not align with the project's objectives. The limited applicability due to its high specificity, the need for precise targeting making it impractical in general environments, and its high production costs classify the laser injection attack as unsuitable for this project.

2.2.3 Ultrasonic Sound Waves Jamming Attack

Ultrasonic sound waves are those that travel at frequencies above 20 kHz, exceeding the range of human hearing. This type of sound wave can be used to perform jamming attacks on microphones, disrupting their functionality. In particular, they can overwhelm the microphone's sensors, which are typically calibrated to capture frequencies within the audible spectrum. When exposed to ultrasonic sound waves, these sensors may register false signals or become saturated, resulting in inaccurate audio captures and, thereby, distorted or unintelligible audio output.

This attack meets all the requirements to be suitable for the project: it can target nearly any everyday microphone, delivers strong performance, and when properly tuned, becomes extremely difficult—if not impossible—for humans to detect. Moreover, its low implementation cost and non-destructive nature make testing the prototype device much more feasible.

CHAPTER 3

Implementation Overview

This chapter presents the project’s objectives, the specific problem it seeks to address, and the challenges encountered during its development. Additionally, it provides a high-level overview of the proposed solution.

3.1 Goal of the project

Nowadays, with the rise of smart devices and the increasing spread of home automation, we are literally surrounded by microphones. All these devices can potentially be used to record sensitive data from our conversations without our consent.

The goal of this project is to create a device capable of (at least partially) deny the aforementioned risk and enhance users’ privacy. The desired device should satisfy the following requirements:

- Effectiveness: the device should deliver perceptually high performance within a reasonable operational range.
- Inaudibility to humans: the device should operate without causing any disturbance during conversations and should only interfere with the functionality of microphones when activated.
- Portability: the device should be designed to be easily transportable.
- Ease of use: the device should be intuitive and user-friendly, ensuring that it can be operated by individuals of varying technical expertise.
- Low energy consumption: the device should be designed to operate with minimal energy requirements.
- Affordability: the device should be produced at minimal cost while ensuring all required functionalities are maintained.

If all the requirements are met, the device will offer an effective solution to the problem, enhancing the privacy of individuals who are often concerned about the risk of being recorded.

3.2 Core Concept

The first step is to formalize the problem and identify the most suitable attack vector that meets the previously aforementioned requirements. Following a thorough analysis, as outlined in Background,

the ultrasonic sound wave jamming attack was determined to be the most appropriate option due to its high applicability, (potential) strong performance, and difficulty for humans to detect.

A cost-effective implementation of this attack involves the use of ultrasonic transducers, which are commonly found in low-cost distance sensors as they operate at the required frequencies (above 20kHz), or they can be bought in bundle at almost any online electronic retailer. Consequently, a signal generator is required to produce the appropriate sound wave for the speaker. Finally, a microcontroller is necessary to orchestrate the operation of the device, managing the control logic and interfacing with the signal generator.

3.3 Key Challenges in Implementing the Core Concept

The core concept satisfies certain requirements, such as inaudibility to humans and low cost. However, aspects like portability, effectiveness, and ease of use are not fully achieved by implementing only the core idea. Furthermore, some properties are inherently interconnected. For example, increasing effectiveness may raise overall costs, reducing affordability, while portability is closely tied to low energy consumption, as high energy demands would compromise the device's practicality.

Therefore, careful evaluation and selection of available market components are crucial to ensure all requirements are met.

3.4 Practical Implementation of the Core Concept

Having outlined the core concept, its development requires additional components to ensure full functionality and satisfy the imposed requirements.

To make the signal effective in a real-world scenario, an audio amplifier is necessary, as the generated signal's power must be boosted to a specific level. By utilizing an external power source, the amplifier module interfaces the microcontroller-signal generator subsystem with the speaker.

The external power source has been implemented as a set of batteries to ensure portability and keep costs low. Specifically, the batteries are lithium-based and are connected together to achieve the required voltage and power.

Finally, a remote-controlled switch has been integrated, enabling the end user to power the device on and off via the *Home* application in the iOS environment or through the lightweight MQTT protocol.

3.5 Final Implementation

At this stage, with all functional and non-functional requirements met through the selected components, the final step is to design the device and integrate all elements into a cohesive unit.

The speakers are embedded into a 3D-printed spherical shell with strategically placed openings to house them. This design enables the jamming attack to be performed in nearly a 360-degree radius, maximizing the coverage of the surrounding area.

Figure 3.1: 3D-printed spherical shell

The shell is mounted on a base that houses the battery along with all the previously mentioned components, including the microcontroller, audio amplifier module, signal generator, and remote-controlled switch. This base provides an organized and concealed arrangement of the internal components, offering the end user a polished and minimalist appearance while maintaining practicality.

Figure 3.2: Final implementation appearance

CHAPTER 4

Implementation Details

4.1 Overview

This section provides a comprehensive explanation of the implementation of the microphone jammer. The primary objective of the project was to interfere with microphones by emitting ultrasonic signals, generated by a system that can be remotely controlled via Apple Home and MQTT protocols.

The following subsections will cover each phase of the development process in detail, from the hardware setup to the software architecture, including the 3D design and final system integration. Each step is described to highlight the key decisions made and the challenges overcome during the development.

4.2 Hardware Setup

4.2.1 Microcontroller - Arduino Uno

An **Arduino Uno** [6] microcontroller was used to manage the system. Arduino was chosen for its ease of use and flexibility, allowing it to interface with a wide range of hardware devices. Below are its key technical specifications:

- **Microcontroller:** ATmega328P
- **Operating Voltage:** 5V
- **Input Voltage (recommended):** 7-12V
- **Input Voltage (limit):** 6-20V
- **Digital I/O Pins:** 14 (6 PWM outputs)
- **Analog Input Pins:** 6
- **DC Current per I/O Pin:** 20 mA
- **DC Current for 3.3V Pin:** 50 mA
- **Flash Memory:** 32 KB (0.5 KB used by bootloader)
- **SRAM:** 2 KB
- **EEPROM:** 1 KB

- **Clock Speed:** 16 MHz
- **Interfaces:** UART, SPI, I2C

The microcontroller was employed to control the signal generator, ensuring it produced the desired waveform at the required frequency.

4.2.2 Signal Generator - AD9833

The **AD9833** [3] signal generator was utilized in this project to produce the ultrasonic signals required to interfere with microphones. The AD9833 is a highly versatile, low-power, programmable waveform generator that can generate *sine*, *triangle*, and *square wave* outputs over a wide frequency range. It employs a **numerically controlled oscillator (NCO)** to ensure precise frequency generation with minimal drift, making it ideal for applications requiring stable and accurate signal production.

Key features of the AD9833 include:

- **Frequency Range:** The AD9833 is capable of generating waveforms from near-DC to several MHz. In this project, it was configured to output signals in the ultrasonic range, specifically between $24kHz$ up to $26kHz$.
- **Low Power Consumption:** With typical power consumption of $20mW$, the AD9833 is well-suited for battery-powered applications. Its energy efficiency made it an ideal choice for the portable jammer system developed in this project.
- **Waveform Generation:** The AD9833 can produce *sine*, *triangle*, and *square waves*, providing flexibility in signal generation. For this project, the *square wave output* was selected due to its efficiency in driving the ultrasonic transducers and maximizing interference with microphone diaphragms.
- **Programmability:** The output frequency and waveform type of the AD9833 are fully programmable via the **SPI (Serial Peripheral Interface)**. This programmability allows dynamic adjustments of the ultrasonic signal, facilitating quick testing of different frequencies to identify the optimal one for microphone disruption.
- **Compact Size:** The AD9833 is available in a small *10-lead MSOP package*, which makes it ideal for compact designs. Its size made it well-suited for the jammer system, where space was limited.

In this implementation, the AD9833 was controlled by an Arduino through the SPI interface, with the output waveform subsequently amplified and transmitted via ultrasonic transducers. This configuration allowed for precise generation of high-frequency signals that were capable of effectively disrupting nearby microphones.

4.2.3 SPI Communication Protocol

The AD9833 programmable waveform generator communicates with the Arduino Uno using the SPI (Serial Peripheral Interface) protocol. SPI is a synchronous serial communication protocol commonly used to exchange data between a master device (in this case, the Arduino) and one or more slave devices (such as the AD9833). The protocol is fast and efficient, utilizing four main signals:

- **MOSI (Master Out Slave In):** Sends data from the master (Arduino) to the slave (AD9833).
- **MISO (Master In Slave Out):** Receives data from the slave. (Not used in this specific application with the AD9833.)

- **SCLK (Serial Clock)**: Synchronizes the communication by generating clock pulses.
- **SS/CS (Slave Select/Chip Select)**: Selects which slave device is active for communication.

In this project, only three of these signals are needed, as the AD9833 is a write-only device, meaning that it does not send data back to the master.

SPI operates by shifting data in or out of the slave device one bit at a time, synchronized by the clock signal. The data is sent over the **MOSI** line, with the clock signal driving the data transfer, and the **SS/CS** line controlling when the slave device (AD9833) is selected for communication.

4.2.4 Pin Configuration for AD9833 Communication

Below are the specific pin configurations used to connect the AD9833 with the Arduino Uno via SPI:

FSYNC (SS/CS) – Pin 10

```
#define AD9833_FSYNC 10 // PIN SS/CS
```

The FSYNC pin is assigned to Pin 10 on the Arduino and serves as the *Slave Select (SS)* or *Chip Select (CS)* pin. The FSYNC pin determines when the AD9833 is selected and ready for communication.

- When the FSYNC pin is set to **LOW**, the AD9833 is selected and activated for communication.
- When the FSYNC pin is set to **HIGH**, the AD9833 is deselected and no communication occurs.

SCLK (SCK) – Pin 13

```
#define AD9833_SCLK 13 // PIN SCK
```

The SCLK pin is defined as the *Serial Clock (SCK)* and is connected to Pin 13 on the Arduino. It generates the clock pulses that synchronize the data transfer between the Arduino and the AD9833.

- For every clock pulse on the SCLK line, one bit of data is transmitted or received.
- The clock signal ensures that both the Arduino and the AD9833 are synchronized during data transmission.

FDATA (MOSI) – Pin 11

```
#define AD9833_FDATA 11 // PIN MOSI
```

The FDATA pin is connected to Pin 11 on the Arduino and serves as the *Master Out Slave In (MOSI)* pin. It is used to transmit data from the Arduino to the AD9833.

- Configuration data and waveform instructions are transmitted from the Arduino to the AD9833 via the MOSI line.
- Data is sent sequentially, one bit at a time, in synchronization with the clock pulses on the SCLK line.

4.2.5 Summary of Pin Roles in SPI for AD9833

- **FSYNC (Pin 10):** Acts as the *Slave Select (SS/CS)* pin to activate or deactivate the AD9833 for communication.
- **SCLK (Pin 13):** Provides the *Serial Clock (SCK)* signal, ensuring synchronized data transfer between the Arduino and AD9833.
- **FDATA (Pin 11):** Serves as the *Master Out Slave In (MOSI)* pin, transmitting data from the Arduino to the AD9833.

This pin configuration allows precise control of the AD9833 using SPI communication, facilitating the generation of the required waveforms at the desired frequency.

4.2.6 Ultrasound Transducers - 250ST180

The ultrasonic transducers 250ST180 [5] used in this project operate at a frequency of 20kHz, which is beyond the audible range for humans. These transducers are particularly effective for disrupting microphones, as they generate high-frequency sound waves that induce vibrations in the microphone diaphragm, impairing its ability to capture sound accurately.

To maximize the interference effect, the placement and orientation of the transducers are crucial. The transducers should be positioned in close proximity to the target microphones and aligned to ensure the ultrasonic waves are directed precisely at the microphones. One key factor influencing the effectiveness of this interference is the beam angle of the transducers, which defines the spread of the ultrasonic waves.

The beam angle determines how focused or dispersed the sound waves are as they propagate. A narrower beam angle results in a more concentrated sound wave, which can enhance the interference effect over longer distances, while a wider beam angle covers a broader area but with less intensity. Given these considerations, both theoretical and empirical analyses were conducted to identify the optimal arrangement of the transducer array, accounting for beam angle, proximity, and orientation to achieve the most effective disruption of microphone performance.

Figure 4.1: Beam Angle

4.2.7 Amplifier - TPA3116D2

The ultrasonic signals generated by the AD9833, controlled via the Arduino, are amplified using the **TPA3116D2** [4], a high-efficiency, Class D audio amplifier from Texas Instruments. The amplifier ensures that the ultrasonic transducers receive a sufficiently powerful signal to produce sound waves with the necessary intensity for effective microphone interference.

The **TPA3116D2** is specifically designed for high-performance audio applications and is capable of delivering output power of up to 50 W per channel (with a $4\ \Omega$ load). Key features of the **TPA3116D2** that make it suitable for this project include:

- **High Efficiency:** The Class D architecture of the amplifier provides high efficiency, with typical values reaching 90% . This reduces heat dissipation and ensures lower power consumption, making it well-suited for applications where energy efficiency is critical.
- **Output Power:** The TPA3116D2 can deliver up to 50 W per channel in stereo mode, or 100 W in mono mode. In this project, the amplifier was used to boost the signal to a level that could drive the ultrasonic transducers effectively, ensuring a strong and clear output at the target frequency of 20 kHz .
- **Low Distortion and Noise:** The amplifier features a low distortion rate, typically less than 0.1% *Total Harmonic Distortion + Noise (THD+N)* at full power, ensuring that the signal remains clean. This is crucial for maintaining the integrity of the ultrasonic signal being transmitted to the transducers, as distortion could reduce the effectiveness of the interference.
- **Thermal and Overcurrent Protection:** The **TPA3116D2** includes built-in thermal and overcurrent protection, ensuring reliable operation even under high-power conditions. This feature enhances the robustness of the system, especially when used in a continuous mode, as is typical in ultrasonic jamming applications.
- **Wide Supply Voltage Range:** The amplifier operates across a wide supply voltage range of 4.5 V to 26 V , providing flexibility in power supply options. In this project, the TPA3116D2 was powered using a suitable DC supply to ensure adequate power delivery to the transducers.

The amplified ultrasonic signals were then fed into the ultrasonic transducers, which required a sufficiently strong input to generate the desired high-frequency output. The use of the **TPA3116D2** allowed for an efficient and powerful amplification stage, ensuring that the transducers operated at optimal levels to effectively disrupt nearby microphones.

4.2.8 Power Supply

The system is powered by a set of rechargeable lithium-ion batteries [8]. The selection of these batteries was made considering the total power consumption of the system, which includes the Arduino, the TPA3116D2 amplifier, and the ESP8266 Wi-Fi module.

The batteries are characterized by the following specifications:

- **Nominal Voltage:** 3.7 V
- **Capacity:** 2600 mAh
- **Maximum Discharge Current:** 3 A (Continuous)

These batteries were chosen for the following reasons:

- **Portability:** The compact size and rechargeable nature of the lithium-ion cells ensure that the system remains portable and easy to use in various settings.

- **Extended Operation:** With a capacity of *2600 mAh*, these batteries provide a substantial amount of energy, allowing the system to operate for extended periods between charges.
- **Stable Voltage Supply:** The nominal voltage of *3.7 V* is suitable for powering the ESP8266 module and can be regulated to meet the voltage requirements of the Arduino and amplifier.
- **High Discharge Current Capability:** The maximum discharge current of *3 A* ensures that the batteries can handle the peak currents required by the TPA3116D2 amplifier during operation.

The use of batteries ensures reliable power supply, contributing to the overall portability and efficiency of the system. Their high energy density and stable performance make them an ideal choice for this application.

4.2.9 ESP8266

For remote control of the jammer, the **ESP8266** [7] Wi-Fi module was employed. This module connects to a local Wi-Fi network and is configured to receive commands via the MQTT protocol and Apple HomeKit, enabling control of the jammer's operation from a mobile device or other connected clients.

The **ESP8266** is a low-cost, highly-integrated Wi-Fi microchip designed for a variety of wireless communication applications. Its key features include:

- **Built-in Wi-Fi Connectivity:** The ESP8266 includes an integrated 2.4 GHz Wi-Fi transceiver, providing reliable wireless communication. It supports the IEEE 802.11 b/g/n Wi-Fi standards, ensuring compatibility with most Wi-Fi networks.
- **Processing Power:** The module is equipped with a 32-bit RISC processor, running at up to *160 MHz*, and includes built-in memory, which supports the execution of complex tasks and protocols directly on the module.
- **Flexible Communication Protocols:** The ESP8266 supports multiple communication protocols, including TCP/IP, UDP, HTTP, and MQTT. In this project, MQTT was used to facilitate communication between the module and the remote control interface.
- **Integration with Apple HomeKit:** The ESP8266 was configured to work with Apple HomeKit, enabling seamless integration into the Apple ecosystem. This setup allows the jammer to be controlled using Apple's Home app or via Siri voice commands.
- **Low Power Consumption:** The module supports various power-saving modes, making it suitable for battery-operated applications. It can operate efficiently in both active and sleep modes, contributing to the overall energy efficiency of the system.
- **GPIO Pins and Interfaces:** The ESP8266 features multiple General Purpose Input/Output (GPIO) pins that can be used for interfacing with external hardware, such as sensors and actuators. For this project, GPIO pins were used to control the power to the jammer.

The ESP8266 was configured to connect to a local Wi-Fi network and receive commands via MQTT messages. This setup allows users to remotely manage the jammer, turning it on or off through a mobile device or other networked clients. The integration with Apple HomeKit further enhances usability, providing a user-friendly interface for controlling the system.

4.2.10 SRD-05VDC-SL-C Relay Module

To control the power supply of the jammer, an **SRD-05VDC-SL-C** [10] relay module was used. This relay module is a key component in switching the high-power signals required for the ultrasonic transducers and other parts of the system.

The **SRD-05VDC-SL-C** is a general-purpose electromagnetic relay with the following features:

- **Coil Voltage:** The relay operates with a coil voltage of 5 V DC , which is compatible with the voltage levels provided by the ESP8266 and other control circuits in the system.
- **Contact Configuration:** It has a Single Pole Double Throw (SPDT) configuration, which includes one common contact (COM), one normally open contact (NO), and one normally closed contact (NC). This allows for versatile switching applications, enabling the relay to connect or disconnect the power supply to the jammer as required.
- **Maximum Switching Current:** The relay can handle up to 10 A at 250 V AC or 30 V DC , making it suitable for switching relatively high currents and voltages used in the jammer system.
- **Contact Material:** The contacts are made of Silver Alloy (AgSnO_2), which provides durability and resistance to electrical arcing, ensuring reliable operation over time.
- **Physical Size:** The relay is compact, with dimensions of approximately $29\text{ mm} \times 12.5\text{ mm} \times 23\text{ mm}$, making it easy to integrate into various circuit designs.
- **LED Indicator:** The module includes an onboard LED indicator that illuminates when the relay is activated, providing a visual confirmation of its status.

In this project, the **SRD-05VDC-SL-C** relay is mounted on a dedicated adapter board designed for the ESP8266. This adapter board simplifies the connection between the relay and the ESP8266 by providing appropriate pin mappings and necessary connections. The relay module is used to control the power supply to the jammer, allowing the ESP8266 to switch the jammer on or off remotely.

The relay's high current handling capability ensures that it can manage the power requirements of the jammer's circuitry safely and effectively. Its integration into the project helps in achieving reliable and controlled operation of the system.

4.3 Software Development

In this section, we will analyze the software code used in the project in detail. The software development process encompasses the creation of the code to control the AD9833 signal generator and the TPA3116D2 amplifier, as well as the integration of the ESP8266 for remote control. The following subsections provide a comprehensive overview of the code structure, libraries used, and key functionalities implemented.

4.3.1 Arduino Source Code

The Arduino source code is responsible for controlling the signal generation and amplification components of the system. The code is written in *C++* using the Arduino Integrated Development Environment (IDE). It utilizes specific libraries to facilitate communication and control:

Libraries Used

- **AD9833.h** by Rob Tillart: This library simplifies the management of the AD9833 signal generator by abstracting the low-level SPI commands into high-level functions.

Code Overview

The code begins with the inclusion of necessary libraries and the definition of pin configurations. The key components of the code are as follows:

- **Initialization:** The code initializes the serial communication for debugging and sets up the AD9833 signal generator using the `AD9833.begin()` function.
- **Waveform Configuration:** The waveform type is set to a square wave using `ad9833.setWave(AD9833_SQUARE1)`, and the initial phase is configured to zero.
- **Frequency Sweeping:** In the main loop, the code performs a frequency sweep by iterating through a predefined set of values. These values are read from program memory (PROGMEM) and used to adjust the output frequency of the AD9833.

```
#include <AD9833.h>
#include <avr/pgmspace.h>

#define AD9833_FSYNC 10

AD9833 ad9833(AD9833_FSYNC);

const uint8_t randomized[] PROGMEM = { /* Randomized Values*/ };

void setup() {
    Serial.begin(9600);
    Serial.println("AD9833 Sweep Test");

    ad9833.begin();

    ad9833.setWave(AD9833_SQUARE1);
    ad9833.setPhase(0);
}

void loop() {
    for (uint16_t i = 0; i < sizeof(randomized); i++) {
        uint8_t rand_val = pgm_read_byte_near(randomized + i);

        ad9833.setFrequency(24000 + rand_val, 0);

        delay(100);
    }
}
```

4.3.2 ESP8266 Code

The ESP8266 module is used to enable remote control of the jammer via a Wi-Fi network. The provided code implements both MQTT and Apple HomeKit protocols to facilitate this control. Below is an overview of the key components and functionalities of the ESP8266 code.

Libraries and Configuration

The ESP8266 code uses several libraries to handle Wi-Fi connectivity, MQTT communication, and HomeKit integration:

- `ESP8266WiFi.h`: Handles Wi-Fi connectivity.
- `PubSubClient.h`: Manages MQTT communication.
- `Arduino.h`: Provides standard Arduino functions.
- `arduino_homekit_server.h`: Manages HomeKit functionalities.
- `wifi_info.h`: Contains Wi-Fi credentials and connection functions.

Code Overview

Global Definitions and Initialization The ESP8266 is configured with the MQTT broker address and initializes both Wi-Fi and MQTT clients.

```
const char* mqtt_server = "broker.hivemq.com";
WiFiClient espClient;
PubSubClient client(espClient);
#define PIN_LED 0
```

Callback Function The `callback()` function processes incoming MQTT messages. It toggles an LED based on the received message and updates the HomeKit state.

```
void callback(char* topic, byte* payload, unsigned int length) {
    Serial.print("Message received on topic: ");
    Serial.println(topic);

    String payloadStr;
    for (unsigned int i = 0; i < length; i++) {
        payloadStr += (char)payload[i];
    }

    if (strcmp(topic, "CosFraGia/JammerProject") == 0) {
        if (payloadStr == "Accendi") {
            digitalWrite(PIN_LED, HIGH); // Turn on
            cha_switch_on.value.bool_value = false; // Update HomeKit state
        } else if (payloadStr == "Spegni") {
            digitalWrite(PIN_LED, LOW); // Turn off
            cha_switch_on.value.bool_value = true; // Update HomeKit state
        }
        homekit_characteristic_notify(&cha_switch_on, cha_switch_on.value); // Notify HomeKit
    }
}
```

MQTT Reconnection The `reconnect()` function ensures that the ESP8266 maintains a connection to the MQTT broker. It attempts to reconnect if the connection is lost.

```

void reconnect() {
    while (!client.connected()) {
        if (client.connect("ArduinoClient")) {
            client.subscribe("CosFraGia/JammerProject");
        } else {
            delay(5000);
        }
    }
}

```

Wi-Fi Setup The `setup_wifi()` function connects the ESP8266 to the specified Wi-Fi network and prints the IP address upon successful connection.

```

void setup_wifi() {
    WiFi.begin(ssid, password);
    while (WiFi.status() != WL_CONNECTED) {
        delay(500);
    }
    Serial.println("WiFi connected");
    Serial.println("IP Address: ");
    Serial.println(WiFi.localIP());
}

```

Setup and Loop Functions In the `setup()` function, serial communication, Wi-Fi connection, HomeKit setup, and MQTT client configuration are initialized. The `loop()` function manages HomeKit interactions and maintains the MQTT connection.

```

void setup() {
    Serial.begin(115200);
    pinMode(PIN_LED, OUTPUT);
    wifi_connect();
    my_homekit_setup();
    client.setServer(mqtt_server, 1883);
    client.setCallback(callback);
}

void loop() {
    my_homekit_loop();
    if (!client.connected()) {
        reconnect();
    }
    client.loop();
    delay(10);
}

```

HomeKit Integration The HomeKit setup and loop functions configure the HomeKit server and handle switch events. The `cha_switch_on_setter()` function updates the switch state based on HomeKit commands.

```

void cha_switch_on_setter(const homekit_value_t value) {

```

```

    bool on = value.bool_value;
    cha_switch_on.value.bool_value = on;
    digitalWrite(PIN_SWITCH, on ? LOW : HIGH);
}

void my_homekit_setup() {
    pinMode(PIN_SWITCH, OUTPUT);
    digitalWrite(PIN_SWITCH, HIGH);
    cha_switch_on.setter = cha_switch_on_setter;
    arduino_homekit_setup(&config);
}

void my_homekit_loop() {
    arduino_homekit_loop();
}

```

Accessory Definition The accessory is defined using the HomeKit library, including characteristics such as the switch state and accessory information.

```

homekit_characteristic_t cha_switch_on = HOMEKIT_CHARACTERISTIC(ON, false);
homekit_characteristic_t cha_name = HOMEKIT_CHARACTERISTIC(NAME, "Switch");

homekit_accessory_t *accessories[] = {
    HOMEKIT_ACCESSORY(.id=1, .category=homekit_accessory_category_switch, .services=(homekit_service_t*)
        HOMEKIT_SERVICE(ACCESSORY_INFORMATION, .characteristics=(homekit_characteristic_t*[]) {
            HOMEKIT_CHARACTERISTIC(NAME, "Jammer"),
            HOMEKIT_CHARACTERISTIC(MANUFACTURER, "Arduino HomeKit"),
            HOMEKIT_CHARACTERISTIC(SERIAL_NUMBER, "1112233"),
            HOMEKIT_CHARACTERISTIC(MODEL, "CostaBot"),
            HOMEKIT_CHARACTERISTIC(FIRMWARE_REVISION, "1.0"),
            HOMEKIT_CHARACTERISTIC(IDENTIFY, my_accessory_identify),
            NULL
        })),
    HOMEKIT_SERVICE(SWITCH, .primary=true, .characteristics=(homekit_characteristic_t*[]){
        &cha_switch_on,
        &cha_name,
        NULL
    })),
    NULL
};

homekit_server_config_t config = {
    .accessories = accessories,
    .password = "121-33-772"
};

```

This section provides an in-depth analysis of the ESP8266 code, highlighting how it integrates with MQTT and HomeKit to manage remote control of the jammer. The code demonstrates how the

ESP8266 handles Wi-Fi connectivity, MQTT messaging, and HomeKit interactions to enable versatile control options.

4.4 3D Design

The 3D design for the project encompasses a custom enclosure to house all hardware components, as well as a spherical structure to hold the ultrasonic transducers. The design was created using OpenSCAD and subsequently 3D printed with a Creality Ender 3 Pro printer.

The enclosure was designed with compactness, portability, and ease of assembly in mind. It includes dedicated compartments for the Arduino Uno, AD9833 signal generator, TPA3116D2 amplifier, ESP8266 module, ultrasonic transducers, and power supply components.

The sphere holding the ultrasonic transducers was designed to maximize coverage, ensuring optimal placement of the transducers to interfere with the largest possible area. The arrangement of the transducers within the sphere was optimized based on theoretical and empirical analysis to create an effective dispersion of ultrasonic waves.

4.5 Assembly and Integration

4.5.1 Physical Assembly

After 3D printing, all hardware components were assembled within the custom-designed enclosure. The connections between the Arduino, amplifier, ultrasonic transducers, and Wi-Fi module were established according to a precise wiring diagram to minimize interference and optimize the use of space. Careful attention was given to the placement of each component to ensure ease of access and proper airflow within the case.

4.5.2 Testing and Calibration

The system was thoroughly tested to ensure the correct emission of ultrasonic signals. Calibration was required to fine-tune the signal frequency generated by the AD9833, ensuring that the transducers emitted at the optimal range. Several iterations of testing were conducted to confirm the system's effectiveness in jamming microphones, with adjustments made to the frequency sweep and signal strength to maximize interference.

CHAPTER 5

Results

Device	Range 1	Range 2	Range 3	Range 4
Smartphone				
PC				
Smartwatch				

Table 5.1: Performance Table

5.1 Known Issues

Although this implementation fully satisfies the requirements outlined in the Implementation Overview chapter and achieves respectable performance, the device is still in its prototype phase and is affected by certain issues:

- Physical barriers: physical barriers can partially or completely negate the jamming attack, as it relies on soundwaves, which are affected by physical laws such as absorption, transmission, and diffraction.
- Range: the current implementation performs adequately at X range, but there is still room for notable improvement.
- Rechargeability of batteries: currently, despite the low energy consumption mitigating the impact of this issue, there is no possibility of recharging the batteries.
- Shell prototype design: The spherical shell's speaker holes are slightly inconsistent in size, with some being larger and others smaller, and the two halves of the sphere are held together in a rudimentary manner.

5.2 Future Work

The concept of this project has successfully achieved its predetermined objectives. However, there are several areas where it could be further improved.

Given more time, most of the known issues could be addressed: increasing the power to the speaker could enhance the operational range and effectiveness of the jamming attack, and higher-quality materials could be used to improve the robustness of the spherical shell and base.

Another significant improvement would be the addition of a white-noise generator with a dedicated speaker, introducing two potential operational modes for the device. The 'Stealth mode' would maintain the current jamming attack functionality, while the 'Paranoic mode' would activate the white-noise speaker to generate additional distortion, providing the user with greater assurance that nearby microphones cannot capture sensitive conversations. Additionally, incorporating the ability to adjust the volume of the white noise could help mitigate the issue caused by physical barriers.

CHAPTER 6

Conclusions

The prototype device successfully achieved its intended task, proving to be an effective solution to the growing issue of privacy violations through unauthorized microphone recordings. The current version of the device meets all the desired properties: effectiveness, inaudibility to humans, portability, ease of use, low energy consumption, and affordability. However, as emphasized throughout the report, the version of the implementation described here represents a prototype, developed with the knowledge, time, and budget available at the time. Several areas for improvement have already been identified, including both existing issues and potential new features. These enhancements aim to make future versions of the device even more reliable, practical, and versatile across different scenarios.

The project has proven to be highly valuable in exploring and delving deeper into a cybersecurity field that is still frequently underestimated and overlooked. The conducted research on microphone technology and state-of-the-art attacks targeting them, paired with the practical experience gained in developing the physical implementation of the device, has provided invaluable insights and a solid foundation for further exploration and innovation in this area of cybersecurity.
